

UAPs Outside the 20-Watt Compression

A Compute-Based Reality Hypothesis

A theoretical framework for
unresolved anomalous phenomena.

The human brain constructs a usable reality from an extreme energy constraint.

Operating on roughly 20 watts of metabolic power, the brain does not receive reality directly. It receives limited electrical signals—a narrow electromagnetic spectrum, pressure variations, chemical interactions. The overwhelming majority of the physical universe never reaches conscious perception.

We do not experience photon streams and pressure waves; we experience compressed objects.

Our experienced reality (O_t) is a highly compressed projection (C) of the underlying state space (R_t). We do not experience millions of independent retinal measurements—reality has already been compressed into objects, locations, and trajectories.

The 20W Ontological Trap forces us to mistake what we perceive for all that exists.

We know our senses are limited—we cannot see neutrinos or radio waves. But we retain a deeper assumption: we assume that reality fundamentally consists of the kinds of things our compressed model already contains (objects, 3D positions, local interactions).

Our biggest compression is not sensory. It is ontological.

Conventional physics evaluates anomalies through the rigid geometry of our compression.

Applying conventional inertia to projected trajectories leads to impossible conclusions.

If an object literally accelerates through the atmosphere at extreme rates, conventional physics dictates massive energy expenditure, shockwaves, and heat. When these are absent, we conclude something cannot move like that. The object appears to break the rules of reality.

The UAP Debate: Moving beyond the false binary of mundane errors vs. interstellar visitors

	Conventional Mundane	Extraterrestrial Craft	CBR Projection (Cross-Compression)
Origin	Sensor errors, balloons	Another star system	Computationally adjacent state space
Travel Method	Drift or conventional flight	Faster-than-light physical propulsion	State transitions projecting as movement
Disappearance	Object moves out of sensor range	Cloaking or rapid spatial exit	Intersection with observer manifold ceases
Required Physics	Known physics	Miraculous exotic engineering	Incorrect ontological abstraction (No physics broken)

Compute-Based Reality (CBR) proposes that space is emergent, not a container.

The Conventional Intuition

The CBR Reversal

CBR reverses conventional intuition. Reality is composed of states and relationships. Space is simply what persistent computational relationships look like from inside the system. Our 3D universe (M^3_t) is just a chart over a much larger state graph.

A transition can be computationally local while appearing geometrically non-local.

The Distance Disconnect

Two states widely separated in our 3D projection may be directly adjacent in the underlying topology. The underlying state simply transitioned; nothing travelled across the intervening physical space at impossible velocities.

Sudden appearance and disappearance resemble a higher-order structure intersecting a flat manifold.

Pre-Intersection

$$\emptyset$$

Intersection

$$U \cap M_{\text{observer}} \neq \emptyset$$

Post-Intersection

$$U \cap M_{\text{observer}} = \emptyset$$

To the inhabitants, an object materialized, changed shape, and vanished. But nothing supernatural occurred. The phenomenon did not cease to exist; its intersection with the observer-accessible manifold simply ceased.

Anomalous UAP kinematics may be analogous to compression artifacts and aliasing.

Actual Physical Phenomenon

Sampled Artifact (Aliasing)

Just as a camera's discrete frame rate makes a wheel appear to spin backwards, our 20W compression samples reality in a way that projects impossible maneuvers. The anomaly exists in the relationship between the phenomenon and the sampling system.

The anomaly is not acceleration without force, but projection without local traversal.

Conventional Physics	CBR Projection
 $C(d^2U/dt^2)$	 $d^2 C(U)/dt^2$
Native Movement (Requires force, heat, sonic booms).	Nonlinear Projection (Apparent motion without local traversal).

Extreme apparent acceleration may just be a nonlinear projection changing rapidly. This provides a conceptual explanation for extraordinary kinematics combined with a total lack of atmospheric displacement or propulsion signatures.

Transmedium traversal is only a barrier within our emergent physical representation.

The Engineering View

The CBR View

SPACE

AIR

WATER

We categorize air, water, and space as radically different because our engineered vehicles interact strongly with physical properties. If a phenomenon operates at a latent state level, these boundaries are just changes in the local state environment, not fundamental physical barriers.

Structured multi-sensor disagreement is a characteristic signature of a cross-compression intersection.

Different sensors perform different compressions. For an ordinary aircraft, these projections converge into a common physical model. For something incompletely represented by our spatial ontology, they might not. $C_{\text{radar}}(U) \neq C_{\text{IR}}(U) \neq C_{\text{IR}} \neq C_{\text{optical}}(U)$. The contradictions are the data.

A testable alternative ontology for the unresolved residual, not a blanket explanation.

The Genuinely Anomalous Residual

NASA explicitly states there is no credible evidence that UAPs are extraterrestrial. AARO reports that most cases appear ordinary, and anomalies are extremely rare.

CBR does not claim all UAPs are projection anomalies. It provides a falsifiable framework for investigating the small fraction of high-quality, unresolved cases that consistently resist conventional four-dimensional trajectory reconstruction.

A CBR UAP Research Programme: Looking for projection effects.

Prediction 1: Structured Disagreement

Better observations yield repeatable, systematically different representations across sensing modalities, rather than converging.

Prediction 2: Motion without Momentum

Observed trajectory vastly exceeds required local energy transfer.

Prediction 3: State Continuity

Discontinuous spatial jumps ($x_1 \rightarrow x_2$) while underlying measurable properties remain continuous.

Prediction 4: Latent Topology

Anomalies correlate with relational synchronization conditions, not geographic locations.

They are not visitors crossing space; they are structures intersecting our geometry.

The deepest question ceases to be *What are they?*

A UAP may not be breaking the rules of reality.
It may be breaking the assumptions of our compression.

The fundamental question we must now ask is:
What reality have to be for something to look like that to us?

**The anomaly may not exist outside reality.
It may exist outside our compression of reality.**
